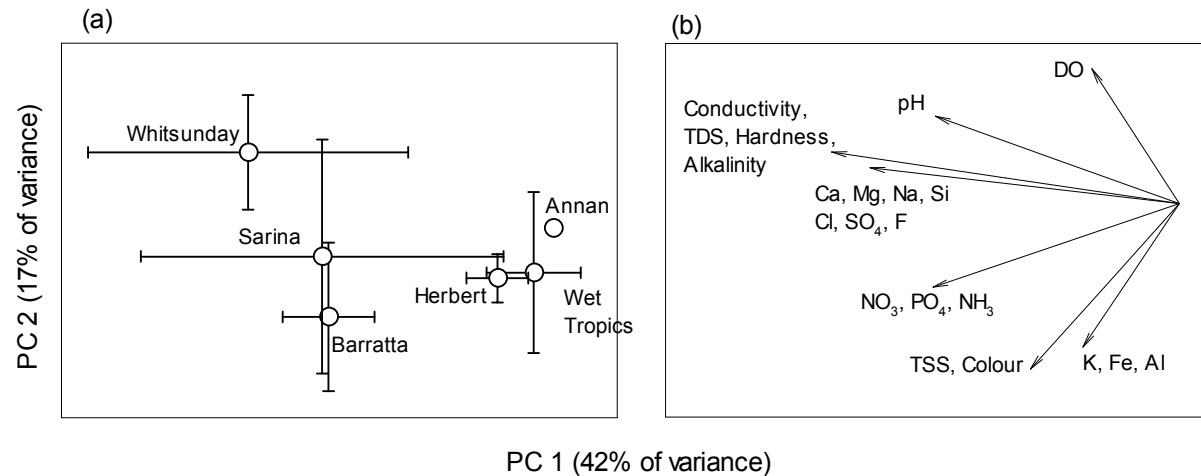

Fig. S1. Principal-component analysis (PCA) of data from ~2000 Queensland Government water-quality samples from 35 sites. (a) Centroids \pm s.d. for each of six areas (relevant data for Atherton and Babinda were not available); (b) vectors showing variables having significant ($P < 0.05$) correlations with the first two axes. Variables were grouped according to similarity of their eigenvector values, and mean values were used to create vectors. Non-significant variables were discharge, turbidity, temperature, boron (B), copper (Cu), manganese (Mn) and zinc (Zn). PCA1 correlated with latitude ($r = 0.829$, $P = 0.006$); PCA2 correlated with total rainfall ($r = -0.703$, $P = 0.035$) and rainfall variation ($r = 0.914$, $P < 0.001$).

Fig. S2. Comparison of richness and SIGNAL scores, plotted against mean sediment size (Phi) between Babinda (closed circles) and Behana (open circles) creeks. Linear regression lines, associated r^2 values and results of ANCOVA comparing streams are shown. d.f. = 19.

Table S1. Locations and characteristics of study streams and associated land use, sorted by latitude and longitude within areas

Dunder is waste from Sarina distillery, applied to land as a fertiliser

| Study area, date | Stream | Latitude (°S) | Longitude (°E) | Altitude (m) | Gradient (%) | Catchment area (km ²) | Percentage forest | Percentage grazing | Percentage cropping | Percentage urban | Other influence |
